### Individual Assignment: MovieRentalApp

This is a project is the Individual Assignment for The Mobile Application Development Module at the University of Buckingham, School of Computing, taught by Nasir Ibrahim

#### **App Description**

MovieRentalApp, provides its users an easy-to-use interface to rent the latest movies. A user can rent a movie as a digital or physical copy, via streaming or receiving a DVD. The user can add multiple Movies to her Cart, as well as update and edit their Cart, before checking out.

**User requirements**

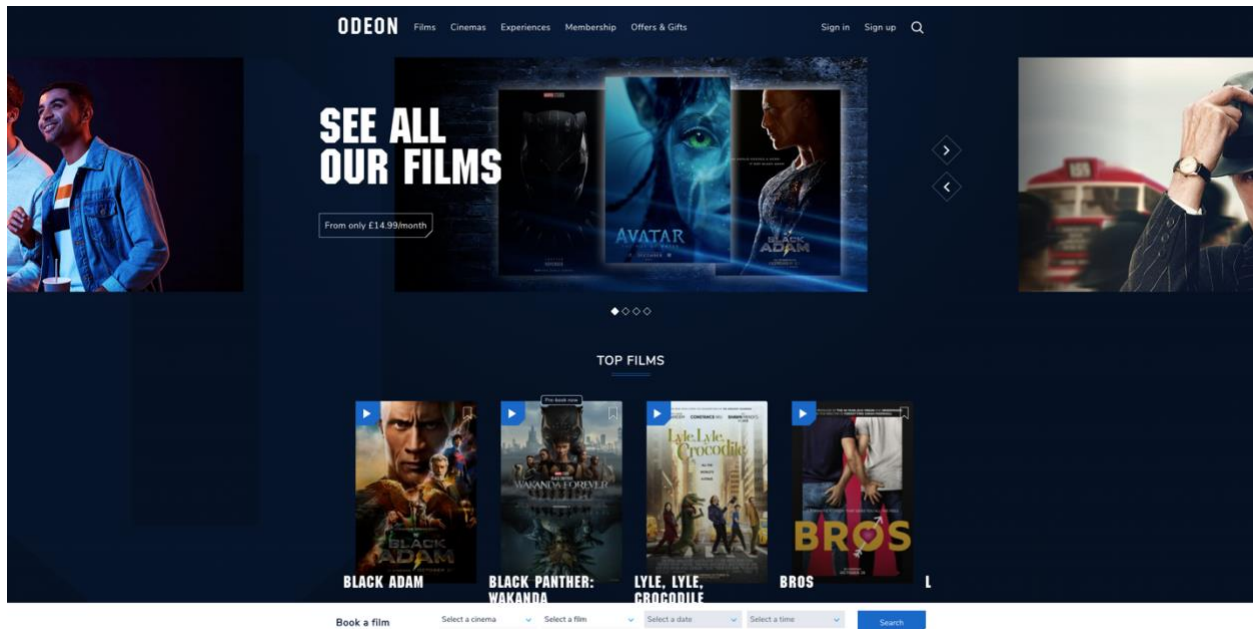

The target user audience are mobile users. Who are keen movie fanatics, they want to be able to quickly and easily see all the latest movies that are available to rent. The users also want to be able to select whether they want to rent a physical or digital copy and how long they want to rent it for. Once the users have selected their Movie order, they want to be able to update, edit and remove them from a Cart. Once the user is happy they want to proceed to a checkout area, where they can proceed to enter their information for rent completion. Another target audience the MovieRentalApp has is the Administration Team, who want to be able to add, update and remove movies from the database.

**Application Functions.**

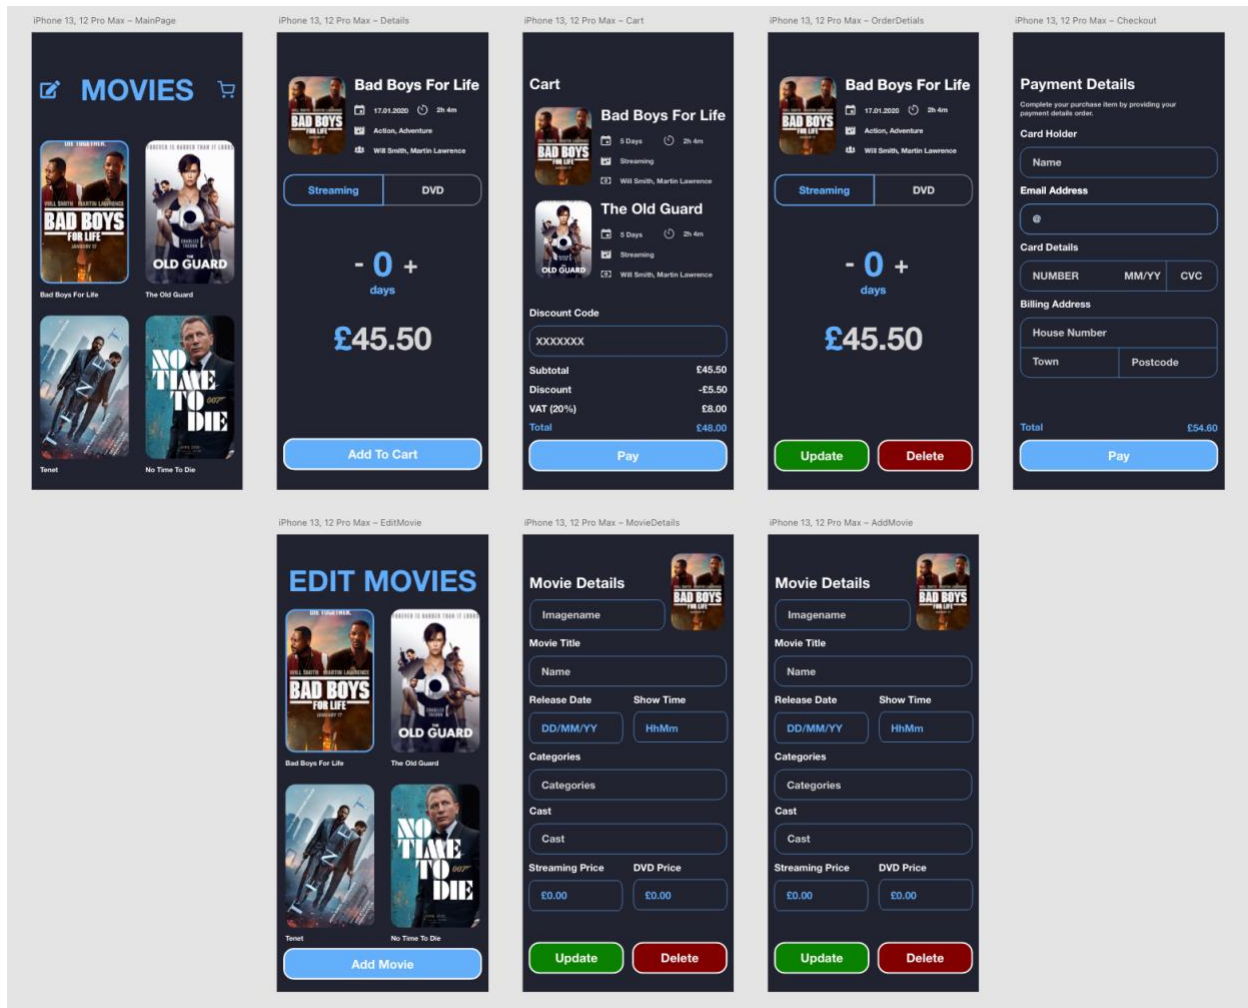

- Customer Functions
  - View Movies
  - Select Movie
  - Select Movie Rental Details
    - Order Type (Digital or Physical)
    - Number of Days
  - See Price
  - View Cart
  - Edit Rentals in Cart
  - Checkout
- Admin Functions
  - View Movies
  - Edit Movies
  - Add Movies

## Designs.

As the target customer audience are keen movie fanatics, in order to continue with Cinema aesthetic. I decided to design the app off Odeon cinemas color scheme.

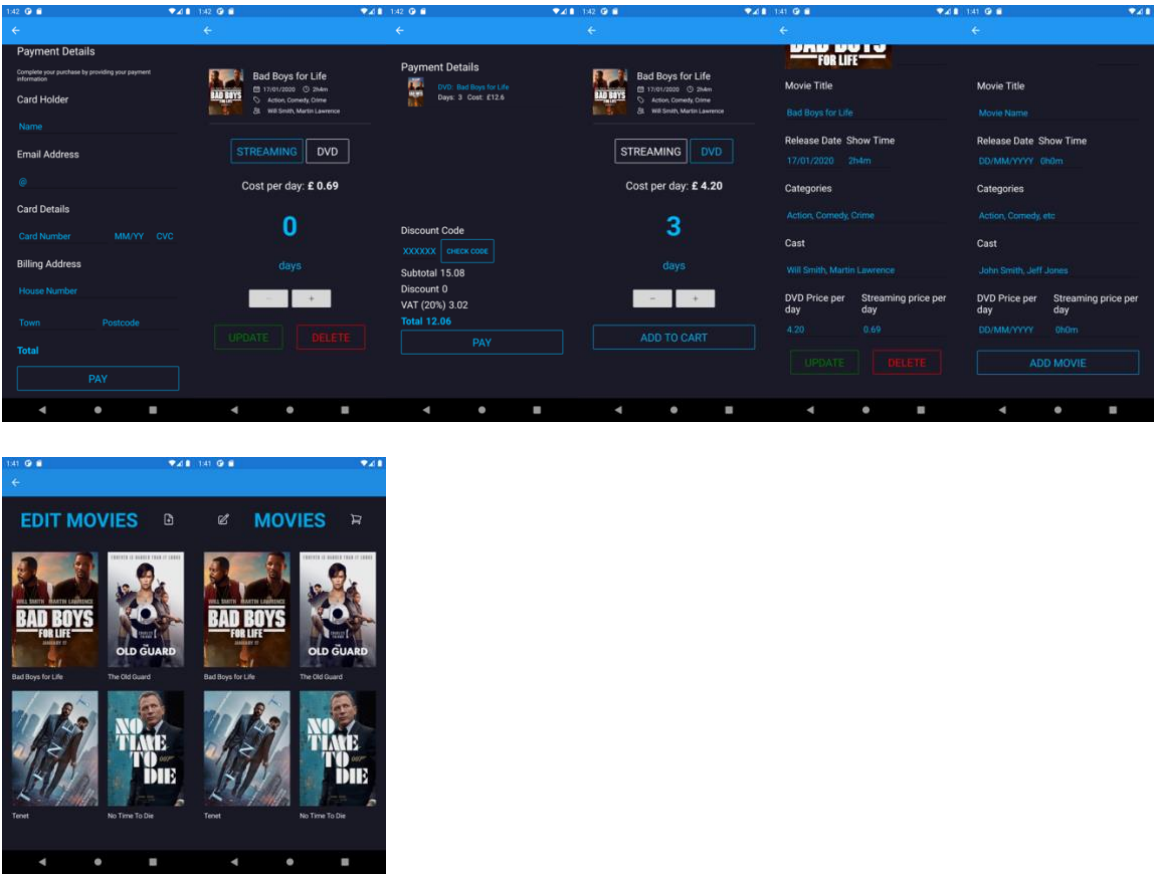

Above is a screen shot of their current website, where their main colors are dark blue, light blue and white. Following with Odeon's color scheme a Wireframe of the application was created in Adobe XD.

In the screenshot above of the wireframe of the MovieRentalApp, there is 8 pages, 5 customer focused and 3 Admin focused.

Prototypes

**How it works**

There are 4 classes,

Ticket, containing all data on a movie

Tickets, collection of tickets using ObservableCollection

Order, containing information on what movie and rental details

Orders, collection of orders using ObservableCollection

Using global functions along with get and set functions, the pages can set and get data from objects within collections.

The Database for movies has been loaded with 4 movies, and there is 1 test item in the checkout.

However both the Tickets (movie) collection and Ordes collection, have the ability for CRUD operations to be completed on them.
